We have developed phased array units for X, K, and Ka bands.

These units include filters, dielectric waveguide transitions, circular polarizers, and spatial radiators. During transmission, they receive signals from the transmitter and perform filtering to suppress spurious emissions, harmonics, and other unwanted signals generated by the transmitter. The dielectric waveguide transition converts the transmission mode to the TE10 mode; a circularly polarized wave is then formed by the circular polarizer and finally radiated into free space through the radiating section. **The polarization rotation direction can be customized as required, or can be set to single-direction operation or dual-direction simultaneous operation.**
